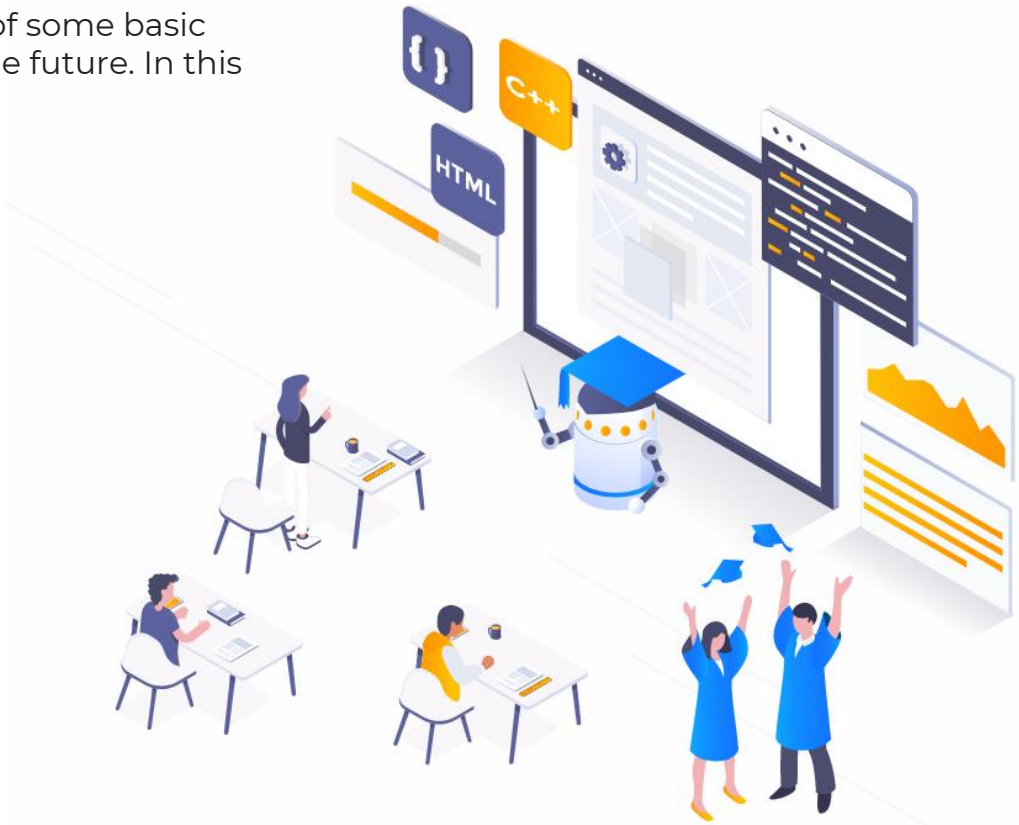
Useful RPA Developing Tips and Tricks

RPA development is a task that takes a lot of attention to detail and perseverance to get it right. The goal is always to get your robot running as robust as possible in the least amount of time possible.

In this lesson we will provide you with some of our tips to help you make your RPA Case a success and save you some time in the process. We will do this by means of some basic tips and tricks that you can apply in all projects that you might create in the future. In this lesson, we will give you some useful knowledge on the following points:

- UiPath Activities
- How to find solutions?
- Useful Resources
- How to use Google?



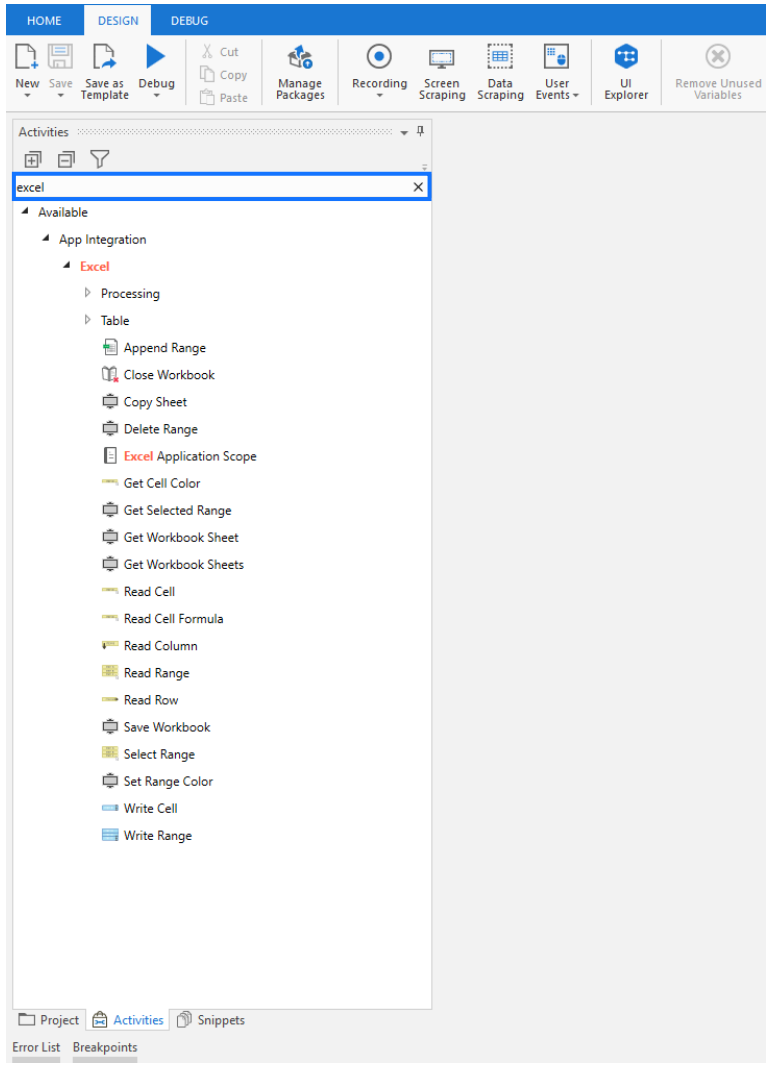
Tips and tricks

Get to know the UiPath activities

UiPath Studio offers a wide range of activities. Take your time to get acquainted with them.

The activities can be found in the activity window on the left side in UiPath Studio. For easy access to an UiPath activity, just press CTRL+ALT+F. You are now automatically in the search bar for activities.

Do you need to automate an Excel process? Just type ‘Excel’ in the activities panel and see what UiPath has to offer.

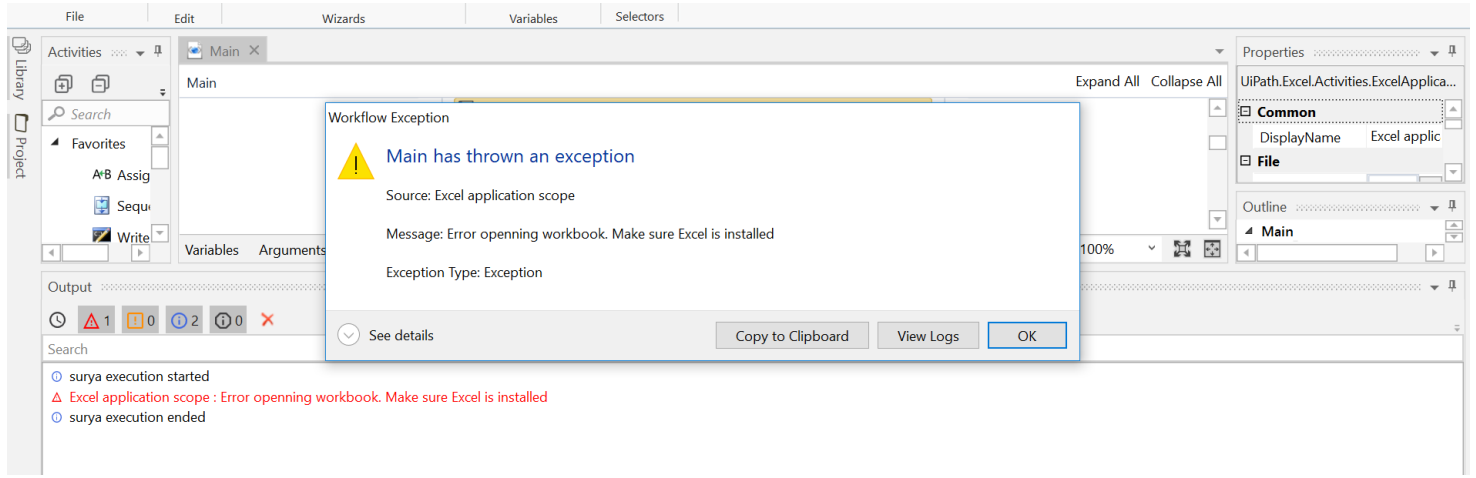


Tips and tricks

How to find solutions?

Did you run into an error? Are you facing an issue? Somebody else probably encountered the same issue you are currently facing.

We have some tips and useful resources where you might find solutions. If you encounter a problem or error, then make use of these helpful tips and tricks. When you do so, you will solve your problem in no time and can continue working on your project.



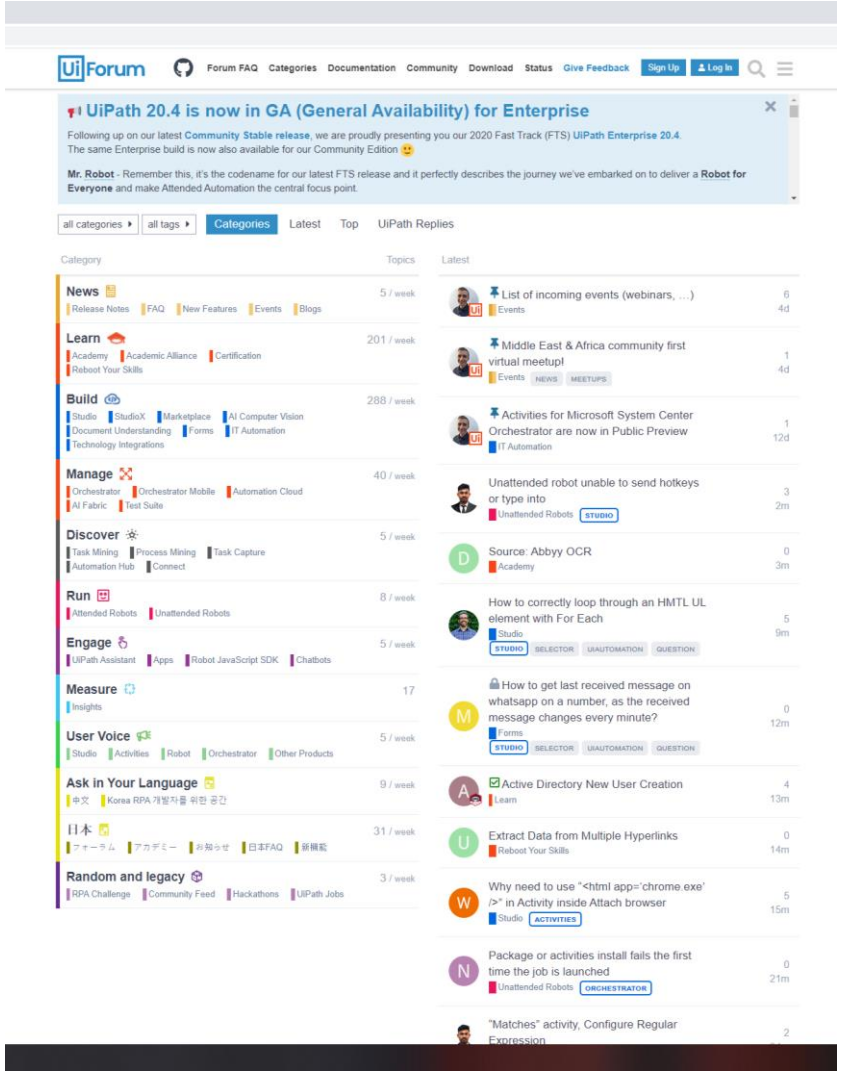
Tips and tricks

Useful resources - UiForum

Most of the time, you are probably not the first one who stumbles upon an error. Instead of trying to figure it out by yourself, you can use the knowledge other developers have acquired before you.

UiPath offers an enormous database on RPA related problems and solutions. You can find this database on [the UiPath Community Forum](). Here, you can find problems that other developers have encountered and therefore reached out for help.

The most relevant page for questions and errors on the UiForum is the Build/Studio page. Here you can browse for relevant subjects, or you can search on keywords by clicking on the magnifying glass.

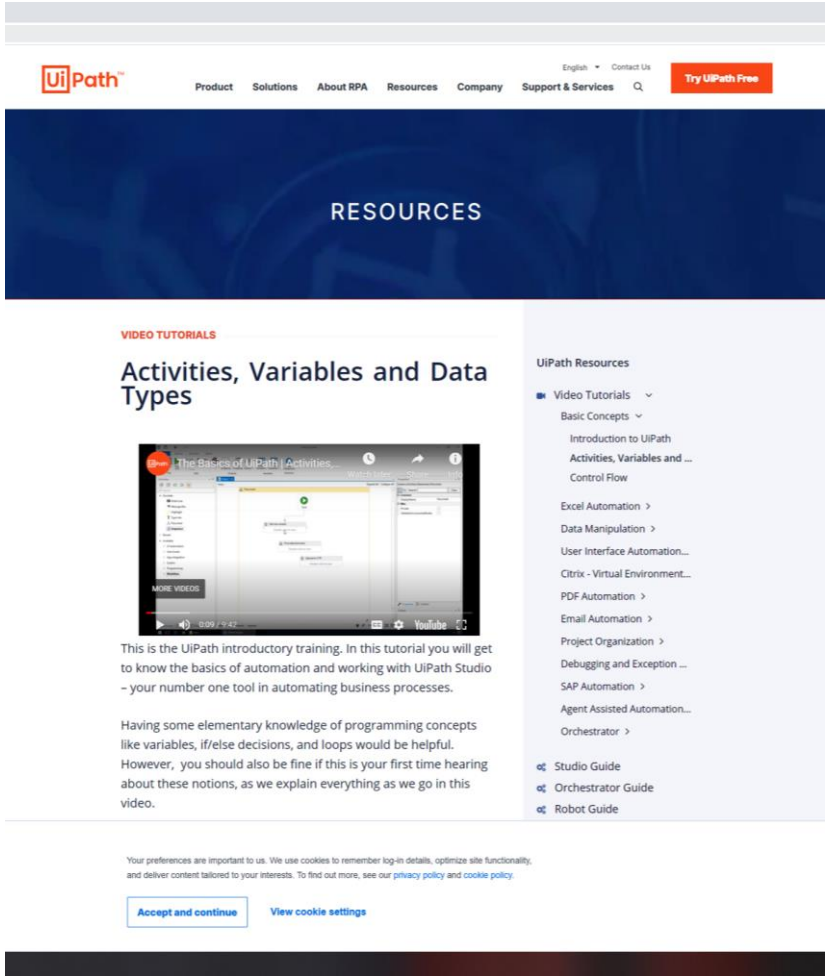


Tips and tricks

Useful resources – UiPath Tutorials

Besides using the knowledge of other RPA developers, you can find your solution in the UiPath RPA Video tutorials.

On this page, you can find all official UiPath videos regarding basic UiPath activities and the debugging of workflows.



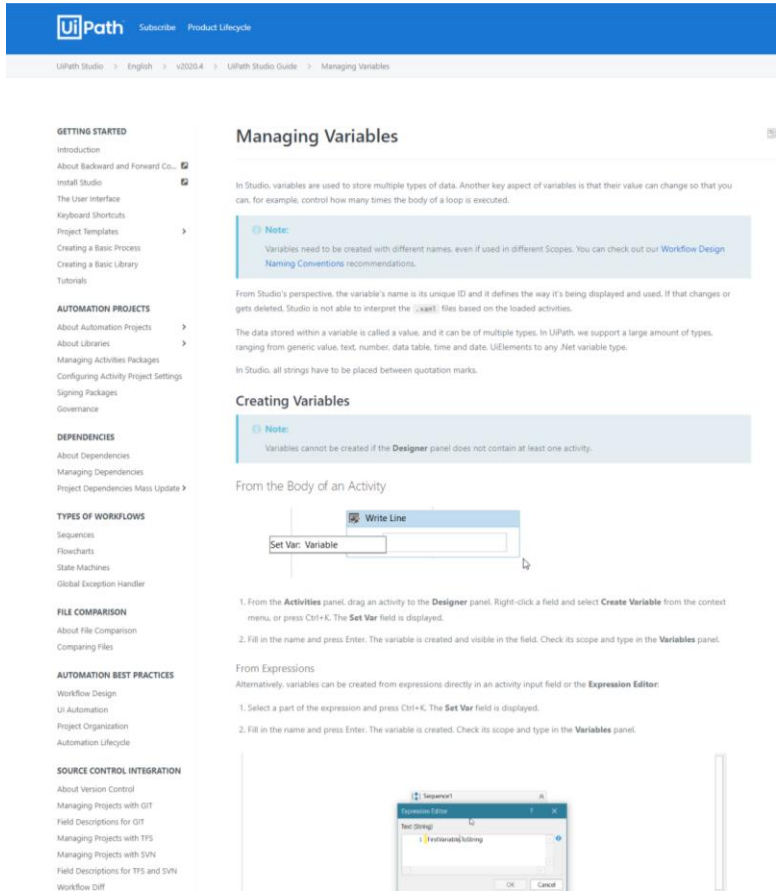
Tips and tricks

Useful resources – UiPath Studio Guide

Another useful resource provided by UiPath is the UiPath Studio Guide. This is a useful tool that explains all properties and activities within UiPath.

The UiPath Studio Guide serves as an online instruction manual. The guide is structured into multiple categories. Each category and subject can be easily accessed through the search bar.

The Studio Guide offers a clear explanation for each subject and is often enriched with a relevant example.

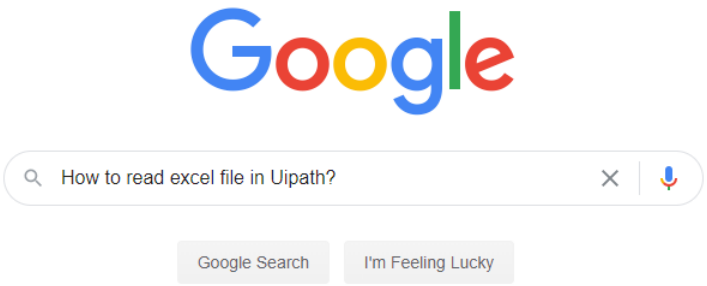


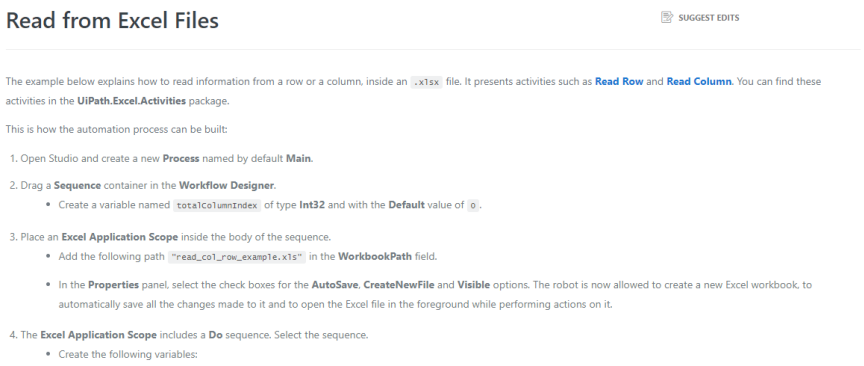
Tips and tricks

How to use Google?

The most useful tool to search on RPA related questions must be Google. Since Google provides access to loads of information, there is a probability that your answer will get lost within all irrelevant search results. Therefore, we have some tips and tricks for searching with Google:

- Make sure you include ‘UiPath’ in your search terms
- If you cannot find the answer by including ‘UiPath’, try ‘VB.NET’
    - VB.NET is the programming language used by UiPath
- Error? Search for [your problem] + [activity] + ‘UiPath’
- If an error message is thrown, copy/paste it in Google search bar





Read from Excel Files

SUGGEST EDITS

The example below explains how to read information from a row or a column, inside an `.xlsx` file. It presents activities such as **Read Row** and **Read Column**. You can find these activities in the **UiPath.Excel.Activities** package.

This is how the automation process can be built:

1. Open Studio and create a new **Process** named by default **Main**.
2. Drag a **Sequence** container in the **Workflow Designer**.
    - Create a variable named `totalColumnIndex` of type **Int32** and with the **Default** value of `0`.
3. Place an **Excel Application Scope** inside the body of the sequence.
    - Add the following path `"read_col_row_example.xls"` in the **WorkbookPath** field.
    - In the **Properties** panel, select the check boxes for the **AutoSave**, **CreateNewFile** and **Visible** options. The robot is now allowed to create a new Excel workbook, to automatically save all the changes made to it and to open the Excel file in the foreground while performing actions on it.
4. The **Excel Application Scope** includes a **Do** sequence. Select the sequence.
    - Create the following variables:

You are all set!
